Clinical Practice Guidelines on Glycaemic Control

Current Trend

1. Hyperglycaemia should be controlled in critically ill patients. Blood glucose level should preferably be controlled below 8 mmol/L. (Grade D Recommendation)

Rationale:
Current evidence suggests that maintenance of normoglycemia reduce mortality and morbidity in critically ill adult patients [1, 2, 6].
Existing evidence showed that the benefit might be more significant with glucose controlled below 6 mmol/L, although levels below 8 mmol/L can also result in survival benefit and probably reduce the risk of hypoglycaemia [3, 4]. This guideline however does not apply to patients suffering from diabetic ketoacidosis or hyperosmolar nonketotic syndrome.

Strategies for Glycaemic Control

1. Hyperglycaemia should be controlled by rapid acting insulin through intravenous administration

Rationale:
Tissue perfusion in critically ill patients are often impaired, making absorption of insulin administered through subcutaneous route less reliable.
In critically ill patients with changing clinical conditions, intravenous infusion is preferable for rapid adjustment.
All published protocols have used intravenous administration of short acting insulin [1, 2, 5, 6]

2. Rate of insulin administration should be titrated according to blood glucose level using a regime based on understanding of the pharmacokinetics and pharmacodynamics of rapid acting insulin.

Rationale:
There are different regimes of insulin administration published but there is no evidence that one is superior to the other.
The half-life of soluble insulin is 2-4 hours but may be longer in critically ill patients. Change in infusion rate may take longer time to establish a new stable state and bolus administration might be necessary.
Caution must be exercised when dealing with patients with severe liver or renal failure.
3. **Regular measurement of blood glucose level at adequate frequency should be carried out to assess the efficacy of glycaemic control and detect presence of hypoglycaemia.**

**Rationale:**
Hypoglycaemia is a recognized problem with glycaemic control [1, 2], although risk of harm (or adverse effects) would be minimized if hypoglycaemia were recognized early by close monitoring. Hypoglycemia in critically ill should be defined at a higher level to avoid neuroglycopenic complications because physiological defenses against low blood glucose are hampered in these patients and there are few warning signs in unconscious or sedated patients. In order to reduce the risk of inadvertent hypoglycaemia, a constant caloric source is desirable, be it enteral, or parenteral.

Blood glucose should be monitored more frequently (e.g. hourly) when rapid changes are anticipated, e.g.
- during initiation, adjustment or cessation of insulin therapy
- during initiation, adjustment or cessation of inotrope/pressor therapy
- during initiation or cessation of steroid therapy
- during initiation, adjustment or cessation of nutritional support
- when significant changes in clinical condition occur

The frequency of monitoring can be lowered when the following conditions are satisfied:
- blood glucose level is stabilized
- no significant change in nutritional intake
- no significant change in clinical condition

Whole blood instead of capillary blood should be used for measurement of blood glucose level because of the possible inaccuracy associated with the latter [7, 8, 9].

4. **If blood glucose is measured by sending specimen to the laboratory, the turn around time should be short enough to allow rapid adjustment of insulin infusion.**

**Rationale:**
Blood glucose measured by the laboratory should be more accurate. However, as the administration rate of insulin may need to be adjusted frequently the turnaround time cannot be too long.

5. **If blood glucose is measured using point-of-care testing system, operators should be properly trained and the device properly calibrated and maintained.**

**Rationale:**
This is in line with the recommendations of the Hospital Authority to ensure that measured results are reliable. [10,11]

Sample Clinical Practice Protocol on Glycaemic Control

1. **Objective**
   To achieve a tight glycaemic control (maintaining blood glucose level of 5-8 mmol/L) despite stress related to critical illness.

2. **Scope**
   It is **NOT intended** for management of **Diabetic Emergencies**, such as diabetic ketoacidosis or hyperosmolar nonketotic coma.

   It is applicable for all patients managed in the ICU for whom details of blood glucose control is not mentioned in the clinical guideline for that particular disease/condition.

3. **Definitions**

<table>
<thead>
<tr>
<th>Role</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Senior</td>
<td>Medical practitioner registered as critical / intensive care specialist or an experienced medical practitioner as assigned by the director of the unit</td>
</tr>
<tr>
<td>MO</td>
<td>Registered medical practitioner after ICU orientation</td>
</tr>
<tr>
<td>RN</td>
<td>Registered nurse after ICU orientation</td>
</tr>
</tbody>
</table>

4. **Responsibilities**

   4.1 **Senior** shall:
      Supervise & assist MO and RN on carrying out the protocol

   4.2 **MO** shall:
      - Decide on whom should be included / excluded for the protocol
      - Prescribe and determine insulin dosage when blood glucose level is >20 mmol/L

   4.3 **RN** shall:
      - Monitoring of blood glucose level
      - Adjust insulin infusion when blood glucose level is within 0-20 mmo/L
      - Report to doctor when indicated

5. **Procedures**

   5.1 Initiation (Appendix A)

<table>
<thead>
<tr>

<td>5.1.2 Monitor Blood Glucose Assay (BGA) every 4 hourly</td>
<td>RN</td>
</tr>
<tr>
<td>5.1.3 Start enteral feeding or dextrose-containing IV fluid</td>
<td>MO / RN</td>
</tr>
<tr>
<td>5.1.4 Look up the Insulin Slide scale for the bolus dose, infusion rate (“Start”) and time for next BGA</td>
<td>RN</td>
</tr>
<tr>
<td>5.1.5 Prescribe PRN insulin bolus on the pre-printed Insulin Administration / Test strip glucose Monitoring Form (Appendix B)</td>
<td>MO</td>
</tr>
<tr>
<td>5.1.6 Prepare insulin by diluting 50 units (0.5 ml) of Actrapid into 49.5 ml 0.9% NS to 50 ml if necessary</td>
<td>RN</td>
</tr>
<tr>
<td>5.1.7 Administer the bolus dose and the infusion of insulin</td>
<td>RN</td>
</tr>
<tr>
<td>5.2 Monitoring of blood glucose</td>
<td></td>
</tr>
<tr>
<td>5.2.1 Monitor blood glucose level using BGA every 30 minutes to 4 hourly as indicated on the Insulin Slide Scale Rule</td>
<td>RN</td>
</tr>
<tr>
<td>5.3 Titration (Appendix A)</td>
<td></td>
</tr>
<tr>
<td>5.3.1 Nurses should decide the titration when BGA is within 0-20 mmol/L</td>
<td>RN</td>
</tr>
<tr>
<td>5.3.2 Make a decision for a bolus dose, change of infusion rate and time for next BGA on every BGA, using the Insulin Slide Scale Rule</td>
<td>RN</td>
</tr>
<tr>
<td>The decision depends on</td>
<td></td>
</tr>
<tr>
<td>- The current blood glucose level; and</td>
<td></td>
</tr>
<tr>
<td>- The trend using the previous blood glucose level</td>
<td></td>
</tr>
</tbody>
</table>
5.3.3 **No insulin** for at least 4 hours if BGA is <3 mmol/L
   - Consider starting a D20 infusion if frequent D50 boluses are required

5.3.4 **Do not**
   - Increase infusion rate if the last change is an increase within 8 hours
   - Decrease infusion rate if the last change is a decrease within 2 hours

5.3.5 Round off infusion rate to highest 0.5 mL/hr no greater than the calculated value

5.3.6 Keep a minimum infusion of 0.5 mL/hr in patient with insulin dependent diabetes

5.3.7 Bolus dose should be administered as indicated in the Insulin Slide Scale Rule, though infusion rate is not changed

5.3.8 Check the pump & IV line for insulin infusion regularly

5.4 Management of Excessive Hyperglycaemia (>20 mmol/L)

5.4.1 Inform MO if blood glucose level is >20 mmol/L

5.4.2 Look for correctable cause of the excessive hyperglycaemia
   - Insulin pump failure
   - Disconnection of insulin
   - Extravasation
   - Bolus administration of dextrose

5.4.3 Determine a bolus dose of insulin and the new insulin infusion rate
   - It is NOT usually appropriate to increase infusion rate more frequent than once every 4 hours

5.5 Fasting (Appendix E)

5.5.1 Insulin infusion should be stopped temporarily when
   - Fasted for an operation/procedure
   - Total parental nutrient infusion is stopped
   - Feeding being interrupted & resumption was not expected
Part II

Hospital Authority Central Committee on Intensive Care

<table>
<thead>
<tr>
<th>Action</th>
<th>Responsible</th>
</tr>
</thead>
<tbody>
<tr>
<td>with 2 hours (e.g. NG tube slipped out &amp; pending confirmation by X-ray)</td>
<td></td>
</tr>
</tbody>
</table>

5.5.2 - Decide on the need for insulin during fasting. Dextrose-Potassium-Insulin (DKI) infusion may be preferred for insulin dependent diabetic patients
- One may also choose to keep a 0.5mL/hr infusion in these patients

5.5.3 - Monitor blood glucose using BGA according to the Insulin Slide Rule

5.5.4 - If feeding is restarted within 6 hours
- Resume insulin infusion at the previous rate of infusion
- Give a bolus & check next BGA according to the Insulin Slide Rule
- Continue with titration as usual (See 5.3)

5.5.5 - If fasting is >6 hours
- Start dextrose-containing IV fluid infusion if not on one
- Follow the protocol as if starting again. (See 5.1)

5.6 Termination

<table>

8. Appendix

Appendix A: Flow Chart for Starting & Titrating

Start

- ICU admission
  - Diabetic emergency?
    - Yes: Manage as per unit protocol
    - No: Blood Glucose Assay (BGA) ≥ 7.8
      - Yes: Start NG feeding or dextrose-containing DYP
        - Start insulin infusion (on the same line for DYP)
      - No: Give regular insulin or D5W IV
        - Determine time for next BGA
  - No: Check BGA
    - Yes: Stop insulin
      - Give bolus of insulin or D5W IV
      - Change insulin infusion
        - Inc. / Inc. infusion
          - Increase
            - Last change: 20% up
            - Last change: 20% down
            - 0.5 unit/h for 2-3 hours
          - Decrease
            - Make change accordingly
  - No: Ignore change
    - Keep a minimum of 0.5 units on D5W

Hospital Authority
Central Committee on Intensive Care
Appendix E: Flow Chart for Fasting

1. Fasting
   - On protocol already:
     - Yes: Resume
     - No: Expected >2hrs
       - Yes: Stop infusion
       - No: Continue BGA monitoring according to Slide Rule
2. Fast >6hrs:
   - Yes: Start dextrose-containing IV fluid
   - No: Resume feeding
3. Check BGA
   - Look up Slide Rule
   - Give bolus if required
   - No need to adjust infusion rate
   - Determine time for next BGA
4. Resume

Start
